Outline Quantum Error Correction Syndrome extraction Stabilizer formalism Experimental Design Surface code Transmon gubits Physical realization Implemented quantum error correction scheme Functionality of stabilizers Detection of general errors Results

Single-shot histograms and state tomography

Conclusions

D PHYS

#### Classical error correction

- Classically, only one possible type of error: bit flip (0  $\leftrightarrow$  1)
- Easy solution: redundant coding, e.g.,

$$0_L = 000$$
,  $1_L = 111$ 

Detect and fix by parity checks (or counting)

#### Quantum error correction

• Can still detect bit flips, e.g., by measuring parity with  $Z_1Z_2$  and  $Z_2Z_3$  (same bit  $\rightarrow$  +1):

```
Z_1 Z_2 |000\rangle = |000\rangleZ_1 Z_2 |100\rangle = - |100\rangle
```

• Qubits have phase: how to correct for phase flips?

 $Z_1 Z_2 |000\rangle = (+1) |000\rangle$  $Z_1 Z_2 (-|000\rangle) = (+1)(-|000\rangle)$ 

.

#### Quantum error correction

- Phase flips mean we need more complex encoding schemes: this is the crucial part of QEC
- Example: Shor code,

$$|0\rangle_{L} = \frac{1}{2\sqrt{2}}(|000\rangle + |111\rangle)(|000\rangle + |111\rangle)(|000\rangle + |111\rangle)$$

- Bit flips:  $Z_i Z_{i+1}$ ,  $Z_{i+1} Z_{i+2}$
- Phase flips:  $X_1 \cdots X_6$ ,  $X_4 \cdots X_9$

### Syndrome extraction

- Another problem: measurement of quantum states is destructive
- Solution: measure correlations, output on "ancilla" qubits

Example: bit flip on  $|\psi\rangle = \alpha |000\rangle + \beta |111\rangle$ 

### Stabilizer formalism

Stabilizer group

$$\mathcal{S} = \{S_1, S_2, \dots, S_n\}$$

- Stabilizers commute, have eigenvalues  $\pm 1$
- Space of codewords is intersection of λ = +1 eigenspaces of S<sub>i</sub> (stabilizers should not affect codewords)
- Allows for specific errors, whose corresponding operators anticommute with one S<sub>i</sub>

### Stabilizer formalism

• Example: 3-qubit repetition code,

$$|0\rangle_L = |000\rangle$$
,  $|1\rangle_L = |111\rangle$ 

• Stabilizer group

$$S = \langle Z_1 Z_2, Z_2 Z_3 \rangle = \{ I, Z_1 Z_2, Z_2 Z_3, Z_1 Z_3 \}$$

• Bit flip on qubit *i* can be detected

## Surface code

- Code qubits (purple) and syndrome/ancilla qubits (green: bit-flip and yellow: phase-flip) at sites of 2D lattice
- Stabilizer code, nearest-neighbor connectivity, decoupled code qubits ⇒ high fault-tolerant error thresholds, scalable geometry

- $\{ |0\rangle, |1\rangle \} \approx \{ |N_g\rangle, |N_g+1\rangle \}$  on island (Cooper pair box)
- Single-qubit gates via Jaynes-Cummings:  $g_i(a\sigma_i^+ + a^{\dagger}\sigma_i^-)$
- 2-qubit gates implemented by virtual photon exchange:  $H_{int} = \frac{1}{2}g_ig_j(\Delta_i^{-1} + \Delta_j^{-1})(\sigma_i^+\sigma_j^- + \sigma_i^-\sigma_j^+)$
- Single-shot readout of qubit state via dispersive phase shift converted via mixer to voltage signal:  $\omega_r + (g_i^2/\Delta_i)\sigma_i^z$

QIP lecture slides, Blais et al., Phys. Rev. A (2007)

#### Physical realization

Primitive tile of surface code: 2 code qubits (next-nearest neighbors), each coupled to ancilla qubits via superconducting coplanar waveguides

## Quantum error correction scheme

#### [2,0,2] code

- prepare code word  $|\psi\rangle = \frac{1}{\sqrt{2}} (|00\rangle + |11\rangle)$  and initialize ancilla qubits as  $|0\rangle$  and  $|+\rangle = \frac{1}{\sqrt{2}} (|0\rangle + |1\rangle)$
- infuse error  $\epsilon$  on one code qubit
- parity check stabilizers ZZ and XX implemented with CNOT gates
- · syndrome readout on ancilla qubits

**D**PHYS

## Parity check stabilizers and error detection

#### stabilizers

$$|\psi\rangle = \frac{1}{\sqrt{2}} (|00\rangle + |11\rangle) \text{ is eigenstate of } ZZ \text{ and } XX \text{ with eigenvalue 1}$$

$$= [I \otimes |0\rangle\langle 0| \otimes I + I \otimes |1\rangle\langle 1| \otimes X] \cdot [|0\rangle\langle 0| \otimes I \otimes I + |1\rangle\langle 1| \otimes I \otimes X]$$

$$= [|0\rangle\langle 0| \otimes |0\rangle\langle 0| + |1\rangle\langle 1| \otimes |1\rangle\langle 1|] \otimes I + [|0\rangle\langle 0| \otimes |1\rangle\langle 1| + |1\rangle\langle 1| \otimes |0\rangle\langle 0|] \otimes X$$

### Parity check stabilizers and error detection

#### action on qubits after error $\epsilon$

error $\epsilon$	code qubits	syndrome qubits
1	00 angle + $ 11 angle$	00 angle
X	01 angle + $ 10 angle$	10 angle
Ζ	00 angle -  11 angle	01 angle
Y	01 angle -  10 angle	11 angle

 $\Rightarrow$  single-qubit error detection possible

#### General error detection

arbitrary single-qubit error 
$$\boldsymbol{U} = \exp\left(-i\frac{\theta}{2}\hat{\boldsymbol{n}}\cdot\vec{\sigma}\right)$$

error	syndrome	probability of measuring
Ι	00	$\cos^2\left(rac{ heta}{2} ight)$
Х	10	$\sin^2\left(\frac{\theta}{2}\right)n_x^2$
Ζ	01	$\sin^2\left(\frac{\theta}{2}\right)n_y^2$
Y	11	$\sin^2\left(\frac{\theta}{2}\right)n_z^2$

· discretization of errors via projective measurements

#### State tomography and single-shot histograms

#### ETHzürich

# Single-shot correlated syndrome measurements for arbitrary errors

#### ETHzürich

# Single-shot correlated syndrome measurements for arbitrary errors

## Conclusions

- implemented a scalable system using nearest-neighbor coupled superconducting qubits
- · implemented high-fidelity one- and two-qubit gates
- · achieved high single-shot assignment fidelities
- enabled detection of arbitrary single-qubit errors via non-demolition measurements

## Circuit decomposition

- State preparation of next-nearest neighbor code qubits (Q<sub>1</sub>, Q<sub>3</sub>) is mediated by bit-flip syndrome qubit (Q<sub>2</sub>)
- Error  $\varepsilon$  controllably introduced via single-qubit rotations about *X*, *Y*, or *Z* axes (*e.g.*  $X_{\pi/3}$  or *XY*)
- Stabilizers implemented with ZZ (bit-flip) and XX (phase-flip) gates
